

Hosting a Static Website with Docker

Objective

Deploy a static website from the template within a Docker container and expose it on a local machine using port redirection (Port 8080 on the host to Port 80 in the container).

Implementation Steps

Step 1: Create the Dockerfile

The **Dockerfile** serves as the blueprint for the container. Create a file named Dockerfile (no extension) in project root with the following content:

Dockerfile

```
FROM nginx:alpine
COPY ./usr/share/nginx/html
EXPOSE 80
```

Step 2: Build the Docker Image

Navigate to the project folder in the terminal and run the build command. This creates a reusable image named mywebsite001.

```
docker build -t mywebsite001 .
```

Step 3: Run the Container with Port Mapping

To access the website on localhost:8080, map the host's port **8080** to the container's port **80**.

```
docker run -d -p 8080:80 --name amber-folio-container mywebsite001
```
